

METROPOLITAN NEUROLOGICAL INSTITUTE

Department of Neurodiagnostics & Clinical Neurophysiology

PATIENT: Jane Doe DOB: 10/14/1978 ID: NX-884920
EXAM DATE: October 08, 2026 REFERRING: Dr. S. Vance, MD
PROCEDURE: Routine 30-Minute Video EEG

CLINICAL INDICATION

34-year-old patient evaluated for single episode of unprovoked lightheadedness and transient staring spell. Rule out epileptiform activity.

TECHNIQUE

Digital electroencephalogram recorded using the International 10-20 system of electrode placement. Intermittent photic stimulation (1-20 Hz) and 3 minutes of hyperventilation were performed. Continuous single-lead EKG was monitored.

FINDINGS

BACKGROUND: The resting background consists of a well-formed, symmetric 9.5-10 Hz posterior dominant alpha rhythm with eyes closed, which attenuates promptly upon eye opening. Anterior channels show low-voltage fast beta frequencies.

ACTIVATION PROCEDURES: Hyperventilation for 3 minutes produced transient mild diffuse theta slowing that returned to baseline within 45 seconds following cessation. Intermittent photic stimulation demonstrated symmetric photic driving at 10 and 12 Hz without photoparoxysmal responses.

TRANSIENTS: No focal or generalized spike-and-wave discharges, polyspikes, or sharp waves were detected. No clinical or electrographic seizures occurred during the recording session.

IMPRESSION

1. Normal 30-minute awake and drowsy routine electroencephalogram.
2. Well-organized posterior alpha rhythm with appropriate reactivity.
3. No epileptiform discharges or electrographic seizure activity observed during this recording.
